[Cannot be displayed due to rights restrictions] If applies, then we start by defining the initial positions of the various objects. Then we define how light rays that pass close to the lens are bent in the same way, no matter what the angle between the light and the lens is. In this program, we define a light cone that represents all the possible positions of light passing through the cluster at any point in time. Next, we define the radius of the cluster, the distance from us to it, and the mass distribution. After that, we calculate how the light cones are bent and we define the percentage of the area of the light cones that are bent. After that, we calculate the light cones for the source as seen from the centre of the cluster. Finally, we redraw the light cones and save the result on your computer. Finally, we explain some effects of using the program and describe how you can save and load images in your computer. Einstein Ring: The program is composed by 18 frames. In each frame, a circle is drawn with the radius of the Einstein ring. Each frame contains four parameters: the first one is the angle, the second one is the value of the distance of the first object, the third one is the mass of the first object, the last is the angle of the second object. All angles are in radians, and the values are in Mpc (1000 km/s for the speed of light). Observers coordinates are the same in each frame. This is, you can move with the mouse the position of the observers to see the changes in the image. When you leave the observer at a point, the mouse will automatically return in the position where you left it. You can draw the source and the observers with the mouse. When you draw the observers, the program only uses data at the back of the observers, so it does not affect the parameters of the lens. To help you draw the observers with the mouse, the program provides two arrows with the same direction for you. You move the arrows, and the mouse follows you. The arrows change their position and direction automatically in order to fit the mouse position. The arrows can be turned off, and the position and direction can be changed in the properties tab. The values of the parameters are taken from a grid with 100x100 points. Each point is spaced 0.05 radians, and it represents values of the mass of the first object from 0.0005 to 0.6, and of the distance of the first object from 0.05 to 400 Mpc. Each point represents the mass of the second object from 0.0001 to 0.6. The distance of the second object is calculated from the observer and the first object position. All the mass values and distance of the objects are in Mpc. The value of the mass will be smaller than 1 because there is a limit for the mass of an object. When the distance of the object is 0, you will not be able to see a real image because the light ray will not pass through the object. You can also change the grid used to draw the images. Draw the Camera: The camera can be turned on or off, and it can be moved, with the mouse, to change the position of the observers. The observers coordinates are computed from the position of the camera. The angles of the 3a67dffeec

Gravitational lensing is caused by the mass of a galaxy or cluster of galaxies. Gravitational lensing, is the deflection of light caused by the gravity of the deflection of the lens and the gravitational field of a galaxy or cluster of galaxies. For example, if a galaxy is large and located close to another galaxy, a distant observer will see the galaxy appear slightly larger than it actually is, like the moon behind Venus. This is because the light from the galaxy is deflected by the galaxy's mass. For example, if we were to drop a billiard ball into a pool of water, the water would bend around the billiard ball. The billiard ball is not acting as a gravitational lens, the water is acting as a gravitational lens. However, if a galaxy is located close to us and is large enough, then the galaxy will act as a gravitational lens. The image of a background galaxy can be magnified, distorted or multiplied depending upon the position of the background galaxy with respect to the galaxy cluster. The magnifying or demagnifying effect of a cluster of galaxies may be used in astronomy. Magnification of a distant galaxy or cluster of galaxies can be used to trace the distribution of matter in the early universe. To see a giant cluster, one must see a red cluster with a significant red background light. When viewed from a distance, the cluster appears like a long thin elongated shadow, with the galaxies along the length of this shadow. Each galaxy is magnified by the cluster, making the cluster appear like a magnifying glass as seen from the outside. This magnifying and demagnifying effect may be used to measure the distribution of matter in the early universe, and it may be used to measure the mass and distance of the cluster. To study the distant universe, astronomers use photographs called CCD's, which record the intensity of the light as it passes through the telescope. The images of the distant galaxies that may be visible are quite faint and very difficult to see with the unaided eye. To study these faint distant galaxies, astronomers use a special telescope that collects a lot of photons. To see this faint image of a distant galaxy, we need to use a telescope with an extremely sensitive CCD. To collect enough photons, astronomers use a special sensitive CCD called a detector array. Each pixel of the camera is set in a specific location in the array. Each pixel

What's New In Gravitational Lensing?

The gravitational field of a mass can bend light rays passing near it. The effect depends on the relative velocity of the source and the lens. On the other hand, Einstein's Theory of General Relativity says that the geometry of the spacetime can be modified by a mass. This modification can be modeled by a curvature of the space. Light travelling through such curved spacetime is called Gravitational lensing. With this lensing, light rays are bent and become distorted. The effect can change the position of the image as well as the shape of the image. Dynamics of the lensing effect: As the light rays from the source approach the mass, they are bent and become distorted and form an image of the source. The effective distance between the source and the image is called the Einstein Radius. The position of the image depends on the mass of the lensing object and the distance of the source from the lens. As the mass increases, the Einstein Radius also increases. The image appears closer to the lensing object. As the mass increases, the Einstein Radius also increases. The image appears closer to the lensing object. Since the position of the image depends on the position of the source with respect to the lensing mass, the direction of the image also depends upon the position of the source. With respect to the lensing mass, the source appears at two locations. This is called two image system. Image Magnification: If a point source lies exactly on the Einstein radius, the lensing object magnifies the light of the source to its full extent. In this case, the image magnification will be infinity. However, this will only happen when the following two conditions are fulfilled. The system should be aligned so that light rays can travel exactly through the Einstein Radius. The source should be exactly on the Einstein radius. This magnification is called Strong Lensing. In strong lensing, image magnification is much larger than that in weak lensing. Weak Lensing: With weak lensing, the image magnification is less than the full image magnification. In such a case, the distortion does not have a drastic effect on the image. The image is smaller than it would be without the lensing object. The lensing effect of gravitational field of massive object can be modeled by the following metric: where a, b and d are known constants and c is a lensing parameter. The gravitational deflection angle

**System Requirements For Gravitational Lensing:**

MUST HAVE A DVD-ROM DISC DRIVE AND A CONSOLE TO RUN THE GAME DVD-ROM DRIVE: DVD-R, DVD+R, DVD+RW, DVD-RW, DVD-R DL, DVD+RW DL, DVD-RAM, DVD+RW, DVD+RW DL, DVD-RW, DVD-R, DVD+R, DVD+R DL DVD-ROM - DVD-ROM DISC: DVD-ROM MEDIA: DVD-ROM, DVD-RW, DVD+RW, DVD
